

1   **Title:** System and Method for Password Authentication for Non-LDAP Regions

2   **Inventors:** Barbara Huff, Howard Pfeffer, Michael Gazillo and Jack Cashman

3   **Field of the Invention**

4           This invention relates generally to connection to the Internet for computers that  
5   are not within their original ISP region. More particularly, the present invention is a  
6   system and method for a dial-up roaming architecture that allows Internet connections for  
7   individuals who are not within their original ISP region.

8   **Background of the Invention**

9           Internet connection is typically accomplished by an Internet Service Provider  
10   (ISP) signing up an individual who can then sign on to the Internet via connectivity that is  
11   provided by the ISP. This typically takes the form of a dial-up modem or other type of  
12   Internet connection via the ISP. In the case of a cable internet infrastructure, the  
13   connection is via a cable modem. In the case of a digital subscriber line (DSL) internet  
14   infrastructure, the connection is via a DSL modem. Thereafter, the user can access the  
15   Internet based upon the speed of the connection to the ISP.

16           A problem occurs when an individual user is no longer present within the region  
17   that is covered by the cable or DSL ISP. This occurs when individuals are traveling or  
18   “roaming” to an area other than the area where service is provided by the user’s ISP.

19           When using a cellular telephone, this procedure is very commonly encountered by  
20   travelers who go from one geographic region to another. Basically travelers are then  
21   assigned to a roaming status and their presence within a particular calling area is noted  
22   with information subsequently provided to the home network, allowing home network to  
23   contact the user who is “roaming.”

1 To solve this problem, currently many users keep a dial-up ISP such as the  
2 Microsoft Network to allow them to have access to the Internet when they are away from  
3 home. This avoids some of the issues associated with different formats that support dial-  
4 up roaming but does not allow, for example, access to the features of a cable internet  
5 connection.

6 Currently, one such protocol that can be used as a directory service to allow  
7 people to locate other people on the Internet is called the Lightweight Directory Access  
8 Protocol or LDAP. LDAP is a directory service specification that is generally accepted  
9 in the Internet. Such a directory service allows people to locate other people or services.  
10 Such a directory service is basically a database that can be searched and manipulated in a  
11 number of ways to display information about a network and its resources. One such use  
12 is to create and manage user accounts including access by registered users to LDAP  
13 enabled networks.

14 Although LDAP service is widely accepted over the Internet, there are many  
15 Internet Service Providers who are not LDAP compatible or enabled. These non-LDAP  
16 networks may be affiliated with other networks which are LDAP enabled. In such cases  
17 it is difficult to verify that a user is authorized to use a non-LDAP network when the user  
18 is trying to access the network via dial-up connection. While LDAP does provide a  
19 good solution to support and authenticate users who are roaming, for those ISPs who are  
20 not LDAP enabled, to upgrade to a standard LDAP architecture requires expensive  
21 architectural changes that many ISPs are not inclined to make.

22 Many such non- LDAP ISPs use different subscriber management systems  
23 (generally referred to herein as SMS) with differently formatted databases. If a user is

1 roaming and is attempting to connect to as a subscriber from a non- LDAP region, any  
2 subscriber management system in the non- LDAP region would need to be kept in  
3 synchronization with an authentication database that exists in centralized LDAP database.  
4 To date, there is no efficient access to data for authentication purposes from a non- LDAP  
5 region to an LDAP region.

6 What is therefore required is a system and method for allowing users to roam  
7 outside of their home regions and to log on to their respective ISPs via dial-up  
8 networking whether the home region is LDAP enabled or not.

#### 9 **Summary of the Invention**

10 It is therefore an objective of the present invention to allow users to roam freely,  
11 yet connect to ISPs at different locations and access their home LDAP enabled  
12 authentication region.

13 It is a further objective of the present invention to allow users to connect to non-  
14 LDAP based authentication regions and to allow subsequent authentication to take place  
15 in an LDAP region.

16 It is a further objective of the present invention to enable a cable modem or DSL  
17 subscriber whose account is assigned to a non- LDAP authenticated site to be able to  
18 roam across the country and have access to such services when they are away from their  
19 cable modem, i.e., connecting to an ISP where they are located.

20 It is a further objective of the present invention to allow access to a cable modem  
21 or DSL infrastructure using a telephone modem dial-up connection.

22 It is yet another objective of the present invention to create a regional remote  
23 authentication dial-in user service (RADIUS) so that secure authentication can take place.

1           It is yet another objective of the present invention to create an authentication  
2   mechanism so that secure authentication can take place regardless of the format of  
3   information in the subscriber management database.

4  
5           These and other objectives of the present invention will become apparent to those  
6   skilled in the art from a review of the specification that follows.

7           The present invention allows a user to be away from the user's cable modem  
8   connection and use a local dial-roaming telephone number, and analog modem, together  
9   with client dial-up software to dial into a local Dial Access Provider (DAP). The DAP  
10   forwards an access request over a Network Access Server (NAS) over a local Internet  
11   network.

12           That request for access proceeds to a corporate RADIUS server which  
13   authenticates the request of the user against an LDAP database. If the user is  
14   authenticated against the directory of the LDAP database, access to the cable modem  
15   services are allowed.

16           Operating in this mode, the NAS operates as a client of the corporate RADIUS  
17   server. The NAS is responsible for passing user information to the corporate RADIUS  
18   server and then acting on the response that is returned.

19           The corporate RADIUS server receives user connection requests, authenticates  
20   the user, and provides configuration information to the NAS to deliver service to the user  
21   who is dialing in.

1           Transactions between the corporate RADIUS server and the NAS are  
2   authenticated through unique identification and exchange of secret information relating to  
3   identity. This information is not sent in the clear over the network.

4           The NAS creates an access request containing such attributes as the user name  
5   and password. The access request is sent to the corporate RADIUS server for  
6   authentication. The RADIUS server then determines to which region the user belongs by  
7   comparing the user's region which is, in part a function of a naming convention such as  
8   (user name@ region.rr.com). This is compared against the region's site type in the  
9   configuration file, that is, LDAP or non- LDAP. If the region is an LDAP region, the  
10   authentication request is forwarded to the regional LDAP database. The LDAP database  
11   then checks its database directory and, if the user is present in the database and password  
12   is correct returns an "accept" message or a "deny" message if the user is not in the  
13   database.

14          If the region in which the user is located is not an LDAP based region, the  
15   corporate RADIUS server will proxy to an appropriate regional RADIUS server. The  
16   regional RADIUS, having received the authentication request in the form of a user name  
17   and CHAP hashed password, retrieves the user's clear text password from the subscriber  
18   management system (SMS) or account management system (AMS) associated with the  
19   non- LDAP region. The system then hashes the clear text password from the SMS/AMS  
20   database using the Challenge Handshake Authentication Protocol (CHAP) and compares  
21   it to the incoming password which is, in the preferred embodiment, also CHAP hashed  
22   and returns an "accept" message if the user is present in the SMS/AMS database or a  
23   "deny" message if the user is not present in the database. When the passwords are CHAP

## **Detailed Description of the Invention**

As noted above, the present invention is a system and method for allowing both LDAP and non-LDAP users to freely roam in different regions of the country and connect to all of the cable or DSL network functionality via dial-up connection.

Users **10** and **12** who are roaming outside of the service region of the cable network provider connect via a dial-up modem connection, or other type of wired or wireless connection to a network access server **14**. Naming conventions for users who are roaming allow user **10**, for example, who is serviced via an LDAP region to access email and other cable network features by virtue of the email address. Regions with LDAP service and regions without LDAP service are differentiated by virtue of their addresses. The network access server **14** connects to the local Internet Service Provider **16** and, via a dedicated communication line **18**, which may, for example, be a T1 line. However, this is not meant as a limitation. Any dedicated high bandwidth line or access both wired and wireless would be suitable for the present invention. The local ISP then connects to the corporate RADIUS server **20** for those users who are in a region that is LDAP enabled. The corporate RADIUS server **20** communicates with the LDAP regional server **24** to determine if the user is in the LDAP database **26**. If the user is in the LDAP database **26**. The regional LDAP server **24** authenticates the user to the corporate RADIUS server **20** which then sends the appropriate accept or deny signal through the communication link **18** over the local ISP **16** through the network access server **14**, to the roaming customer **10**.

If the customer is in a non-LDAP region, customer **12** dials in via the network access server **14**, over the local ISP **16** and again over dedicated network **18** to the

1 RADIUS server **22**. The RADIUS server then proxies the request for access to a regional  
2 RADIUS server **28** which connects to the non- LDAP region server **30** which in turn has  
3 a subscriber management system (SMS) or account management system (AMS) database  
4 **32**. Through a view into the non- LDAP region server **30**, the system determines if the  
5 roaming customer **12** is permitted access. If such access is permitted, a message is sent  
6 by the non-LDAP region server **30** to the regional RADIUS **28** to the RADIUS server **22**.  
7 Thereafter the accept or deny signal is sent via the dedicated network **18** via the local ISP  
8 **16** over the network access server **14** to the roaming customer **12**.

9 In this fashion, roaming customers who are in a region which is non- LDAP  
10 enabled can still use an access cable or DSL service via a regional RADIUS server which  
11 is a relatively inexpensive upgrade to existing systems. Thus, non- LDAP enabled  
12 regions do not have to engage in expensive upgrades in order to allow roaming customers  
13 to have access to their systems.

14 A system and method to allow roaming customers to have access to LDAP or  
15 non- LDAP enabled regions has now been illustrated. It will be appreciate by those  
16 skilled in the art that other variations of the present invention are possible without  
17 departing from the scope of the invention as disclosed.

18  
19  
20

- 1           1.       A method for dial roaming for users having a home non-LDAP  
2           (Lightweight Directory Access Protocol) region to allow access comprising:  
3           dialing into a local dial access provider;  
4           creating an access request ;  
5           forwarding the dial access request to a corporate remote authentication dial-in  
6           user service (RADIUS) server;  
7           proxying the request to a regional RADIUS server associated with the user's  
8           home region;  
9           accessing the regional user database to determine if the user is present in the  
10          regional database;  
11          authenticating the user; and  
12          providing configuration information to the user to allow access to the network.  
13          2.       The method for dial roaming of claim 1 wherein the access request is  
14          forwarded to an access provider via a network access server (NAS).  
15          3.       The method of claim 2 wherein the NAS functions as a client of the  
16          corporate RADIUS server.  
17          4.       The method of claim 1 further comprising:  
18          the corporate RADIUS server determining if the user is a member of an LDAP or  
19          non-LDAP region.  
20          5.       The method of claim 4 wherein the determining if the user is a member of an  
21          LDAP or non-LDAP region is accomplished by reviewing a configuration file  
22          stored in the corporate RADIUS server.
